[TITLE OF THE INVENTION]

Apparatus for synchronized playback of audio data and performance data and method therefor

[SCOPE OF THE PATENT CLAIM]

[Claim 1]

A recorder being characterized by having:

a first receiving means for receiving audio data representing audio waveform of a musical tune;

a second receiving means for receiving control data instructing performance control;

a first generating means for generating a first index indicating a variation tendency for a predetermined time period of the aforesaid audio data;

a second generating means for generating a second index indicating a variation tendency for a time period longer than the aforesaid predetermined time period of the aforesaid audio data; and

a recording means for recording performance data comprising the aforesaid control data and a first time data representing a receiving timing of the control data, comparing the aforesaid first index and the aforesaid second index, detecting rapid variation of the aforesaid audio data and recording a second time data representing a timing of the aforesaid rapid variation.

[Claim 2]

A player being characterized by having:

a first receiving means for receiving performance data having control data for instructing performance control and a first time data instructing an execution timing of said

performance control and second time data representing a timing of a rapid variation of the audio waveform;

a second receiving means for receiving audio data representing an audio waveform of a musical tune;

a first generating means for generating a first index indicating a variation tendency for a predetermined time period of the aforesaid audio data;

a second generating means for generating a second index indicating a variation tendency for a time period longer than the aforesaid predetermined time period of the aforesaid audio data;

a third generating means for comparing the aforesaid first index and the aforesaid second index in order to detect a rapid variation of the aforesaid audio data and generating a third time data representing a timing of the aforesaid rapid variation;

an adjusting means for adjusting the aforesaid first time data based on the time information represented by the aforesaid second time data and the aforesaid third time data; and

a transmission means for transmitting the aforesaid control data at the timing in compliance with the aforesaid first time data adjusted by the aforesaid adjusting means.

[Claim 3]

A recording method being characterized by having:

a first receiving step for receiving audio data representing audio waveform of a musical tune;

a second receiving step for receiving control data instructing performance control;

a first generating step for generating a first index indicating a variation tendency for a predetermined time period of the aforesaid audio data;

a second generating step for generating a second index indicating a variation tendency for a time period longer than the aforesaid predetermined time period of the aforesaid audio data; and

a recording step for recording performance data comprising the aforesaid control data and a first time data representing a receiving timing of the control data, comparing the aforesaid first index and the aforesaid second index, detecting rapid variation of the aforesaid audio data and recording a second time data representing a timing of the aforesaid rapid variation.

[Claim 4]

A playback method being characterized by having:

a first receiving step for receiving performance data having control data for instructing performance control and a first time data instructing an execution timing of said performance control and second time data representing a timing of a rapid variation of the audio waveform;

a second receiving step for receiving audio data representing an audio waveform of a musical tune;

a first generating step for generating a first index indicating a variation tendency for a predetermined time period of the aforesaid audio data;

a second generating step for generating a second index indicating a variation tendency for a time period longer than the aforesaid predetermined time period of the aforesaid audio data;

a third generating step for comparing the aforesaid first index and the aforesaid second index in order to detect a rapid variation of the aforesaid audio data and generating a third time data representing a timing of the aforesaid rapid variation;

an adjusting step for adjusting the aforesaid first time data based on the time information represented by the aforesaid second time data and the aforesaid third time data; and

a transmission step for transmitting the aforesaid control data at the timing in compliance with the aforesaid first time data adjusted by the aforesaid adjusting means.

[Claim 5]

A program which causes a computer to execute:

a first receiving step for receiving audio data representing audio waveform of a musical tune;

a second receiving step for receiving control data instructing performance control;

a first generating step for generating a first index indicating a variation tendency for a predetermined time period of the aforesaid audio data;

a second generating step for generating a second index indicating a variation tendency for a time period longer than the aforesaid predetermined time period of the aforesaid audio data; and

a recording step for recording performance data comprising the aforesaid control data and a first time data representing a receiving timing of the control data, comparing the aforesaid first index and the aforesaid second index, detecting rapid variation of the aforesaid audio data and recording a second time data representing a timing of the aforesaid rapid variation.

[Claim 6]

A program which causes a computer to execute:

a first receiving step for receiving performance data having control data for instructing performance control and a first time data instructing an execution timing of said

performance control and second time data representing a timing of a rapid variation of the audio waveform;

a second receiving step for receiving audio data representing an audio waveform of a musical tune;

a first generating step for generating a first index indicating a variation tendency for a predetermined time period of the aforesaid audio data;

a second generating step for generating a second index indicating a variation tendency for a time period longer than the aforesaid predetermined time period of the aforesaid audio data;

a third generating step for comparing the aforesaid first index and the aforesaid second index in order to detect a rapid variation of the aforesaid audio data and generating a third time data representing a timing of the aforesaid rapid variation;

an adjusting step for adjusting the aforesaid first time data based on the time information represented by the aforesaid second time data and the aforesaid third time data; and

a transmission step for transmitting the aforesaid control data at the timing in compliance with the aforesaid first time data adjusted by the aforesaid adjusting means.

[DETAILED EXPLANATION OF THE INVENTION]

[0001]

[TECHNICAL FIELD OF THE INVENTION]

The present invention relates to an apparatus and a method for playing back performance data including information relating to performance control of a musical tune in synchronization with playback of audio data.

[0002]

[PRIOR ART]

There is an apparatus for reading out audio data from a recording medium such as a music CD (Compact Disc) and generating sounds from the readout audio data to be output as a means for playing back a musical tune. There is an automatic performance apparatus for reading out data including information on performance control of a musical tune from a recording medium such as an FD (Floppy Disk) and for controlling tone generation of a tone generator by using the readout data as another means for playing back the musical tune. There is MIDI data created by complying with the MIDI (Musical Instrument Digital Interface) standard as the data including information relating performance control of the musical tune.

[0003]

Recently, a method for synchronizing the automatic performance with MIDI data with the playback of audio data recorded on the music CD has been proposed. There is a method of using time codes recorded on the music CD as one of them (see patent document 1 and patent document 2, for example). The methods will be explained below.

[0004]

First, the audio data and time codes in the music CD are reproduced by a music CD player. Then, the audio data is output as a sound and the time codes are supplied to a recorder. Herein, the time code is data associated with the certain amount of audio data and each time code represents a lapse of time from the a start of the musical tune to a playback timing of the audio data associated with said time code. The musical instrument is played with the playback of the music CD and the MIDI data are sequentially supplied from the musical instrument to the recorder. The recorder receives the MIDI data from the musical instrument and records the MIDI data on the recording medium with the time

information representing the receiving timing. The recorder receives the time code from the music CD player and records this in the recording medium with the time information representing receiving timing. As a result, a file in which the time code and the MIDI data are mixed is created in the recording medium. In this file, respective time codes and the MIDI data have time information representing lapses of time from the musical tune playback starting timing until respective playback timing.

[0005]

Thus, the audio data of the same musical tune is played back from a music CD after the MIDI data and the time code are recorded on the recording medium, the MIDI data is read out from the recording medium in synchronization therewith and the automatic performance is realized. The operations are as follows.

[0006]

First, the audio data and the time code are reproduced from the music CD by a music CD player. Then, the audio data is output as sound and the time code is supplied to the player of the MIDI data. The player reads out the MIDI data stored in the file based on the time information recorded therewith and sequentially transmits those to a musical instrument capable of automatic performance with the MIDI data. At that time, the player adjusts the time difference between the playback of the audio data of the music CD and the playback of the MIDI data based on the time code received from the CD player and the time code read out from the file together with the MIDI data. As a result, the synchronized playback of the audio data of the music CD and the MIDI data are realized.

[0007]

[Patent Publication 1]: Patent Application No. 2002 - 7872

[Patent Publication 2]: Patent Application No. 2002 - 7873

[0008]

[PROBLEM TO BE SOLVED BY THE INVENTION]

However, the synchronized playback of the audio data of the music CD and the MIDI data is not possible by a method of using the time codes of the music CD for music CDs labeled with different time codes for the same musical tune.

[0009]

Currently, there are lots of music CDs of different versions for the same musical tune. The music CD usually records audio data which the master data of the musical tune is edited by adding acoustic effects such as reverberation thereon. In the music CD of the different version, an offset time until the musical tune starts may differ. A clock speed used for recording the audio data after editing may not coincide with a clock speed used for recording the master data. As a result, the music CD of the different version, which records the audio data edited differently, may be labeled with time codes having slightly different time periods. In such a case, when the MIDI data for synchronized performance created with a conventional technology using the time codes is used for the music CD of the different version for the same musical tune, the musical tune from the music CD and the performance with the MIDI data are shifted at the start of the musical tune, or the musical tune of the music CD and the performance with the MIDI data gradually become shifted even though the musical tune of the music CD and the performance with the MIDI data are synchronized at the start of the musical tune.

[0010]

Accordingly, it encounters a problem that the music CD recording the audio data for the same musical tune based on the conventional technology using the time codes needs different MIDI data for a synchronized performance depending on a variation of time

intervals of the time codes attached to a version of the music CD, respectively.

[0011]

By contemplating the above circumstances, it is an object of the present invention to provide a recorder, a player, a recording method, a playback method and program of performance data such as MIDI data or the like to be played back in synchronization with plural versions of audio data recorded at difference time intervals due to different clock speeds used upon recording for audio data of the same musical tune.

[0012]

[MEANS TO SOLVE THE PROBLEM]

[0012]

To solve the above explained problem, the present invention provides a recorder being characterized by having:

a first receiving means for receiving audio data representing audio waveform of a musical tune;

a second receiving means for receiving control data instructing performance control;

a first generating means for generating a first index indicating a variation tendency for a predetermined time period of the aforesaid audio data;

a second generating means for generating a second index indicating a variation tendency for a time period longer than the aforesaid predetermined time period of the aforesaid audio data; and

a recording means for recording performance data comprising the aforesaid control data and a first time data representing a receiving timing of the control data, comparing the aforesaid first index and the aforesaid second index, detecting rapid

variation of the aforesaid audio data and recording a second time data representing a timing of the aforesaid rapid variation.

[0013]

The present invention provides a player being characterized by having:

a first receiving means for receiving performance data having control data for instructing performance control and a first time data instructing an execution timing of said performance control and second time data representing a timing of a rapid variation of the audio waveform;

a second receiving means for receiving audio data representing an audio waveform of a musical tune;

a first generating means for generating a first index indicating a variation tendency for a predetermined time period of the aforesaid audio data;

a second generating means for generating a second index indicating a variation tendency for a time period longer than the aforesaid predetermined time period of the aforesaid audio data;

a third generating means for comparing the aforesaid first index and the aforesaid second index in order to detect a rapid variation of the aforesaid audio data and generating a third time data representing a timing of the aforesaid rapid variation;

an adjusting means for adjusting the aforesaid first time data based on the time information represented by the aforesaid second time data and the aforesaid third time data; and

a transmission means for transmitting the aforesaid control data at the timing in compliance with the aforesaid first time data adjusted by the aforesaid adjusting means.

[0014]

The present invention provides a recording method being characterized by having:
a first receiving step for receiving audio data representing audio waveform of a musical tune;

a second receiving step for receiving control data instructing performance control;

a first generating step for generating a first index indicating a variation tendency for a predetermined time period of the aforesaid audio data;

a second generating step for generating a second index indicating a variation tendency for a time period longer than the aforesaid predetermined time period of the aforesaid audio data; and

a recording step for recording performance data comprising the aforesaid control data and a first time data representing a receiving timing of the control data, comparing the aforesaid first index and the aforesaid second index, detecting rapid variation of the aforesaid audio data and recording a second time data representing a timing of the aforesaid rapid variation.

[0015]

The present invention provides a playback method being characterized by having:

a first receiving step for receiving performance data having control data for instructing performance control and a first time data instructing an execution timing of said performance control and second time data representing a timing of a rapid variation of the audio waveform;

a second receiving step for receiving audio data representing an audio waveform of a musical tune;

a first generating step for generating a first index indicating a variation tendency for a predetermined time period of the aforesaid audio data;

a second generating step for generating a second index indicating a variation tendency for a time period longer than the aforesaid predetermined time period of the aforesaid audio data;

a third generating step for comparing the aforesaid first index and the aforesaid second index in order to detect a rapid variation of the aforesaid audio data and generating a third time data representing a timing of the aforesaid rapid variation;

an adjusting step for adjusting the aforesaid first time data based on the time information represented by the aforesaid second time data and the aforesaid third time data; and

a transmission step for transmitting the aforesaid control data at the timing in compliance with the aforesaid first time data adjusted by the aforesaid adjusting means.

[0016]

The present invention provides a program which causes a computer execute the processes using these recording method and the playback method.

[0017]

The present invention provides a recording medium recording performance data having control data for instructing performance control and a first time data instructing an execution timing of said performance control and a second time data representing a timing of a rapid variation of the audio waveform.

[0018]

Using the apparatus, method, program and recording medium with said configuration, the time data for the time adjustment is created at a timing when the audio waveform of the musical tune rapidly changes upon recording and playback of the performance data and the transmission timing of the control data by comparing the time

data generated upon recording and the time data generated upon playback. As a result, the synchronized playback of the audio data and the control data is realized.

[0019]

The recorder according to the present invention may include a third receiving means for receiving the time codes representing the playback timing of the aforesaid audio data and the recording means may generate the aforesaid first time data and the aforesaid second time data based on the time information represented by the aforesaid time code.

The player according to the present invention may include a third receiving means for receiving the time codes representing the playback timing of the aforesaid audio data and the aforesaid third generating means may generate the aforesaid third time data based on the aforesaid time code and the aforesaid transmission means may transmit the aforesaid control data based on the time information represented by the aforesaid time code.

[0020]

By using the recorder and the player with this configuration, the time is measured in accordance with the time codes with respect to the audio data which is played back by the player having a bias in the playback speed so that the control data is synchronously played back.

[0021]

In the recorder according to the present invention, the first generating means filters the audio waveform represented by the audio data and extracts the frequency component equal to or lower than the first frequency in order to generate the aforesaid first index; the aforesaid second generating means filters the audio waveform represented by the audio data and extracts the frequency component equal to or lower than the second frequency which is lower than the aforesaid first frequency in order to generate the

aforesaid second index.

In the player according to the present invention, the aforesaid first generating means filters the audio waveform represented by the aforesaid audio data and extracts the frequency components equal to or lower than the first frequency in order to generate the aforesaid first index, and the aforesaid second generating means filters the audio waveform represented by the aforesaid audio data and extracts the frequency components equal to or lower than the second frequency lower than the first frequency in order to generate the aforesaid second index.

[0022]

By using the recorder and player with such a configuration, the time data for time adjustment having preferable time intervals and the accuracy.

[0023]

In the recorder implemented by the present invention, the aforesaid recording means may record the aforesaid second time data in the aforesaid audio data only when the rapid variation has not been detected in the predetermined time period from the timing when the aforesaid rapid variation is detected.

In the player implemented by the present invention, the aforesaid third generating means may generate the aforesaid third time data only when the rapid variation has not been detected in the predetermined time period from the timing when the aforesaid rapid variation is detected.

[0024]

By using the recorder and the player according to this configuration, the time intervals of the time adjustment is properly maintained even when the audio waveform frequently and rapidly varies so that the adjacent time data are not mixed.

[0025]

The player according to the present invention, the aforesaid adjusting means may adjust the playback timing of the aforesaid performance data based on values represented by a regression line or a regression curve acquired by the regression analysis on the aforesaid second time data and the aforesaid third time data.

[0026]

By using the player with such configuration, since the error in the time data for the time measurement is adjusted as a whole, the accuracy of the transmission timing of the control data in the synchronized playback is enhanced.

[0027]

[EMBODIMENT OF THE INVENTION]

[1] First embodiment

[1.1] Structure, function and data format

[1.1.1] Whole configuration

Fig. 1 is a view to show a configuration of a synchronized recorder and player SS implemented by a first embodiment of the present invention. The synchronized recorder and player SS comprises a music CD drive 1, an FD drive 2, an automatic player piano 3, a tone generating portion 4, a manipulating display 5, and a controller 6.

[0028]

The music CD drive 1, FD drive 2, automatic player piano 3, tone generating portion 4 and manipulating display 5 are connected to the controller 6 by communication lines, respectively. The automatic player piano 3 and the tone generating portion 4 are directly connected each other by the communication line.

[0029]

[1.1.2] Music CD drive

The audio data stored in the music CD includes audio data representing audio information and time codes representing playback timings of the audio data. The music CD drive 1 reads out the audio data from the loaded music CD under instructions from the controller 6 and sequentially outputs the audio data included in the audio data. The music CD drive 1 is connected to a communication interface 65 in the controller 6 by a communication line.

[0030]

The audio data, which is output from the music CD drive 1, is 16 bit digital audio data in two channels in left and right quantized at a sampling frequency of 44,100 Hz in 16 bits. The data output from the music CD drive 1 does not include the time code. Since the configuration of the music CD drive 1 is similar to a general music CD drive which is capable of outputting the digital audio data, the explanation will be omitted.

[0031]

[1.1.3] FD drive

The FD drive 2 records SMF (Standard MIDI File) in the FD or reads out the SMF recorded in the FD in order to transmit the readout SMF. The FD drive 2 is connected to the communication interface 65 in the controller 6 by the communication line. Since the configuration of the FD drive 2 is similar to a general FD drive, the explanation will be omitted.

[0032]

[1.1.4] MIDI event and SMF

The SMF is a file including the MIDI event serving as the performance control data complied with the MIDI standard and delta time serving as data representing the

execution timing of the respective MIDI events. The MIDI events and the format of the SMF will be explained with reference to Fig. 2 and Fig. 3.

[0033]

A note-on event, a note-off event and a system exclusive event are shown in Fig. 2 as examples of the MIDI event. The note-on event is a MIDI event which instructs the tone generation of a musical tone and comprises 9nH (n represents a channel number, H represents a hexadecimal number, and which will be the same hereinafter) representing the tone generation, a note number representing a pitch, and a velocity representing the strength of the tone generation (or a velocity of striking a key). Similarly, the note-off event is a MIDI event which instructs the tone extinction of a musical tone and comprises 8nH representing the tone extinction, a note number representing a pitch, and a velocity representing the strength of the tone extinction (or a velocity of releasing a key). On the other hand, the system exclusive event is a MIDI event which transmits, receives or records data formatted by a product or software manufacturer's discretion, and comprises F0H representing a start of the system exclusive event, a data length, data and F7H representing an end of the system exclusive event. In such a way, the MIDI event does not include time information and is used for tone generation, tone extinction of the musical tone and other control in real time.

[0034]

Fig. 3 shows the general overview of the SMF format. The SMF includes a header chunk and a track chunk. The header chunk includes control data relating data format and time units included in the track chunk. The track chunk includes the MIDI event and delta time representing an execution timing of respective MIDI events.

[0035]

The SMF has expressions for delta time, namely, the one is expressed in time called as a clock representing the relative time with respect to a MIDI event immediately before and the other is expressed by a combination time of hour, minute, second and frame to represent the absolute time from the head of the musical tune. To make the explanation easy, the delta time is defined as the absolute time from the base time and is expressed in second in the explanation below.

Moreover, the MIDI data is the comprehensive name for data created by complying with the MIDI standard in the present specification.

[0036]

[1.1.5] Automatic player piano

The automatic player piano 3 is a musical tone generator which outputs an acoustic piano tone and an electronically synthesized piano tone in response to a key manipulation and a pedal manipulation by the user of the synchronized recorder and player SS. The automatic player piano 3 generates a MIDI event in response to the key manipulation and the pedal manipulation by the user and transmits the generated MIDI event. Further, the automatic player piano 3 receives the MIDI event and automatically plays with acoustic piano sounds and electronically synthesized piano tones in response to the received MIDI events.

[0037]

The automatic player piano 3 comprises a piano 31, key sensors 32, pedal sensors 33, a MIDI event control circuit 34, a tone generator 35 and a driving part 36.

[0038]

The key sensor 32 and the pedal sensor 33 are provided on each of the plural keys and the plural pedals of the piano 31 in order to detect the positions of keys and pedals,

respectively. The key sensor 32 and pedal sensor 33 transmit the detected position information, identification number corresponding to each of the keys and pedals, respectively, and detected time information to the MIDI event control circuit 34.

[0039]

The MIDI event control circuit 34 receives the position information of the keys and pedals, respectively, from the key sensors 32 and the pedal sensors 33 together with the identification information of the keys and pedals and the time information, and immediately generates MIDI events such as a note-on event, note-off event or the like from the information in order to output the generated MIDI event to the controller 6 and the tone generator 35. The MIDI event control circuit 34 receives the MIDI event from the controller 6 and transfers the received MIDI event to the tone generator 35 or the driving part 36. Further, the MIDI event control circuit 34 is under the instruction of the controller 6 to determine which the MIDI event received from the controller 6 is transferred to the tone generator 35 or the driving part 36.

[0040]

The tone generator 35 receives the MIDI events from the MIDI event control circuit 34 and outputs the sound information of various musical instruments as digital audio data in the left and right channels based on the received MIDI events. The tone generator 35 electronically synthesizes the digital audio data at a pitch designated by the received MIDI event and transmits it to a mixer 41 in the tone generating portion 4.

[0041]

The driving parts 36 are provided on the respective keys and pedals of the piano 31 and comprises a group of solenoids for driving these and a control circuit for controlling the group of solenoids. When the control circuit of the driving parts 36 receives the MIDI

events from the MIDI event control circuit, it adjusts current to be supplied to the solenoid provided on a corresponding key or pedal in order to adjust magnetic flux generated by the solenoid and the key or pedal is operated in response to the MIDI event.

[0042]

[1.1.6] Tone generator

The tone generating portion 4 receives the audio data from the automatic player piano 3 and the controller 6 and converts the received audio data into sounds to be output. The tone generating portion 4 comprises the mixer 41, a D/A converter 42, an amplifier 43 and a speaker 44.

[0043]

The mixer 41 is a digital stereo mixer which receives plural sets of digital audio data in the two channels, left and right, and converts these into a pair of left and right digital audio data. The mixer 41 receives the digital audio data from the tone generator 35 of the automatic player piano 3 and at the same time, receives the digital audio data, which is read out by the music CD drive 1 from the music CD, through the controller 6. The mixer 41 calculates an average of the received digital audio data and transmits this to the D/A converter 42 as a pair of digital audio data in right and left.

[0044]

The D/A converter 42 receives the digital audio data from the mixer 41 and converts the received digital audio data into the analog audio signal to be output to the amplifier 43. The amplifier 43 amplifies the analog audio signal, which is input from the D/A converter 42, and outputs it to the speaker 44. The speaker 44 converts the analog audio signal, which is input from and amplified by the amplifier 43, into sounds. As a result, the audio data recorded in the music CD and the audio data generated by the tone

generator 35 are output from the tone generating portion 4 as stereo sounds.

[0045]

[1.1.7] Manipulation display

The manipulation display 5 is a user interface when a user of the synchronized recorder and player SS manipulates the synchronized recorder and player SS.

The manipulation display 5 includes key pads when the user depresses to give instructions to the synchronized recorder and player SS and a liquid crystal display for confirming the state of the synchronized recorder and player SS. When the key pad is depressed by the user, the manipulation display 5 outputs a signal corresponding to the depressed key pad to the controller 6. The manipulation display 5 receives bit map data including information of characters and figures and displays the characters and figures based on the received bit map data on the liquid crystal display.

[0046]

[1.1.8] Controller

The controller 6 controls the entire synchronized recorder and player SS. The controller 6 comprises a ROM (Read Only Memory) 61, a CPU (Central Processing Unit) 62, a DSP (Digital Signal Processor) 63, a RAM (Random Access Memory) 64 and a communication interface 65. The components are mutually connected each other through a bus.

[0047]

The ROM 61 is a non-volatile memory for storing various kinds of control program. The control program, which is stored in the ROM 61, includes program for general control routine and program which causes the CPU 62 to execute routines for recording operations and playback operations of the SMF which will be mentioned later.

The CPU 62 is a microprocessor, which executes general purpose processing, and reads out the control program from the ROM 61 and executes the control routines in accordance with the readout control program. The DSP 63 is a processor which permits processing of the digital audio data at a high speed, executes a filtering process necessary for a managing event generation process, which will be mentioned later, on the digital audio data received from the music CD drive 1 and the FD drive 2 by the processor 6, and transmits the acquired data to the CPU 62. The RAM 64 is a volatile memory and temporarily stores the data used by the CPU 62 and DSP 63. The communication interface 65 is an interface which is capable of transmitting and receiving the digital data in various formats, converts the format necessary for digital data transmitted or received between the music CD drive 1, FD drive 2, automatic player piano 3, tone generating portion 4, and manipulation display 5, and relays the data between the respective devices and the controller 6.

[0048]

[1.2] Operation

Next, operations of the synchronized recorder and player SS will be explained.

[1.2.1] Recording operation

First, operations of the synchronized recorder and player SS, when a user of the synchronized recorder and player SS plays a piano in synchronization with the playback of a commercially available music CD and the information of the performance is recorded on an FD as the MIDI data, will be explained. The music CD used during the recording operation, which will be explained below, is called as a music CD-A in order to discriminate the music CD used during the playback operation mentioned later.

[0049]

[1.2.1.1] Start operation of recording

The user sets the music CD-A in the music CD drive 1 and an empty FD in the FD drive 2. Subsequently, the user depresses the key pads of the manipulation display 5 corresponding to the recording start of the performance data. The manipulation display 5 outputs the signal corresponding to the depressed key pad to the controller 6.

[0050]

The CPU 62 of the controller 6 receives the signal corresponding to the recording start of the performance data from the manipulation display 5 and transmits a playback instruction of the music CD to the music CD drive 1. In response to the playback instruction, the music CD drive 1 sequentially transmits the audio data recorded in the music CD-A to the controller 6. The controller 6 receives the data for a pair of right and left channels for every $1/44100$ second from the music CD drive 1. Hereunder, the data values for a pair of the right and left channels are expressed as $(R(n), L(n))$, and the pair of data values or respective sets of data values generated from the pair of data values in the data generation routine for correlation discrimination are called as "sample values". The $R(n)$ and $L(n)$ represent data values in the right channel and the left channel, respectively, and they are either of integers ranging from - 32768 to 32767. n is an integer representing an order of the audio data and increases from the start of the data such as 0, 1, 2

[0051]

[1.2.1.2] Transmission of audio data to tone generating portion

The CPU 62 receives the sample values from the music CD drive 1 and starts time measurement by setting the timing as 0 second. At the same time, the CPU 62 sequentially transmits the received sample values to the tone generating portion 4. The tone generating portion 4 receives the sample values from the controller 6 and sequentially

converts it into sounds to be output. As a result, the user can listen to the musical tune recorded in the music CD-A.

[0052]

[1.2.1.3] Generation of management event

The CPU 62 transmits the received sample values to the tone generating portion 4 and, at the same time, sequentially stores the received sample values in the RAM 64. The CPU 62 stores a predetermined number of sample values in the RAM 64 and transmits an execution instruction, which executes a management event generating process explained hereunder, to the DSP 63. The number of sample values, which are stored in the RAM 64 until the CPU 62 transmits the execution instruction of the management event generation process to the DSP 63, depends on the filter characteristics used in the process which will be explained below. The longer the delay time of the delaying element used in the filter, the larger the number becomes. In the following explanation, it is assumed that the CPU 62 transmits the execution instruction of the management event generating process when the sample values for a second, namely, 44,100 units of sample values are stored in the RAM 64.

[0053]

The management event generation process is a process including a filter process extracting frequency components equal to or lower than a certain frequency on the audio waveform represented by the audio data stored in the RAM 64 and a filter process extracting frequency components equal to or lower than a frequency which is lower than the frequency, and compares the values acquired by the two filter processes in order to generate the management event. The management event is a flag to generate time information used in a timing adjustment process mentioned later.

The management event generating process will be explained with reference to Fig. 4.

[0054]

The DSP 63 receives an execution instruction of the management event generation process from the CPU 62 and reads out first 44100 sets of sample values stored in the RAM 64, namely, $(R(0), L(0)) \sim (R(44099), L(44099))$ (step S1). Hereunder, a series of 44100 sample values are called as "raw audio data" and the raw audio data having $(R(n), L(n))$ as the last one is represented as "raw audio data (n)" if the raw audio data has to be discriminated. In other words, the raw audio data read out by the DSP 63 first in the step S1 is a raw audio data (44099).

[0055]

Subsequently, the DSP 63 executes an arithmetic average operation of the left and right values of the respective sample values of the raw reference audio data and converts the stereo data into a monaural data (step S2). The conversion process into the monaural is a process to reduce the workload on the DSP 63 in processes after this step.

[0056]

Subsequently, the DSP 63 calculates absolute values for the series of sample values converted into the monaural signal (step S3). The process in the step calculates substitute values of power of the respective samples. Since the absolute values have smaller values than square values representing the power and are easily processed, the present embodiment uses the absolute values instead of the square values of respective sample values. Accordingly, the square values may be calculated instead of the absolute values of the respective sample values in this step when the performance of the DSP 63 is high.

[0057]

Subsequently, the DSP 63 filters the series of sample values converted into the absolute values in the step S3 through the low pass filter (step S4). Hereinafter, the values acquired as a result of the processes in the steps S1 to S4 are called as "middle term index" and the middle term index corresponding to $(R(n), L(n))$ is called as a "middle term index (n)". Herein, a cut-off frequency of the low pass filter used in the step S4 is set at 100 Hz. The middle term index (n) indicates a tendency in a middle term in a variation of the audio waveform represented by the series of sample values with respect to n. In other words, the audio waveform represented by the series of sample values goes up and down in a short term and the variations in values of the series of sample values filtered by the low pass filter are suppressed by the plural precedent sample values. As a result, the short term variation component is removed from the waveform represented by the series of the middle term index and the variation in the middle term component and the long term component remains. The series of the middle term indices including the middle term index (n) as the last one, namely, ... the middle term index (n-2), the middle term index (n-1) and the middle term index (n) are created by the process in the step S4. The DSP 63 stores these middle term indices in the RAM 64 (step S5).

[0058]

Subsequently, the DSP 63 filters the series of the middle term indices acquired in the step S4 through a comb filter (step S6). The process in this step is a process which extracts the low frequency component equal to or lower than a certain frequency from the audio waveform represented by the series of the middle term indices. This step is similar to the process using the low pass filter having the cut-off frequency lower than the cut-off frequency of the low pass filter used in the step S4, and the comb filter is used instead of

the low pass filter in the present embodiment because the comb filter applies lower load on the DSP 63 than the low pass filter.

[0059]

Fig. 5 shows a configuration of an example of the comb filter to be employed in the step S6. In Fig. 5, a process represented by a square rectangular means a delay process and k in z^{-k} means that the delay time in the delay process is (sampling cycle $\times k$). As mentioned previously, the sampling frequency of the music CD is 44100 Hz and the sampling period is $1 / 44100$ second. On the other hand, the process represented by a triangle means a multiplication and a value indicated in the triangle means a coefficient of the multiplication. Hereinafter, it is assumed that $k = 22050$, and the frequency components higher than 1 Hz are almost removed therefrom by the filtering process in the step S6. In other words, the audio waveform represented by the series of values acquired by the process in the step S6 is acquired by extracting the long term variation component by removing the middle term variation component from audio waveform represented by the series of the middle term indices.

[0060]

Subsequently, the DSP 63 multiplies the series of values acquired by the filtering process in the step S6 by a positive constant h , respectively (step S7). The multiplication process by the constant h is a process to adjust the frequency to acquire the positive result in a comparing process in a next step S8 and time intervals which acquires the positive results in the comparing process generally become shorter when a value of the constant h becomes small. If the time interval becomes too long, time intervals of the generated management events in step S11 below becomes longer and the accuracy of the timing adjusting process mentioned later become lower. On the other hand, if the time intervals

which the positive results are acquired in the comparing process become too short, the positive results are cancelled by a process in step S10 below one after another; the time intervals of the generated management events also become longer; and as a result, the accuracy of the timing adjusting process becomes lower. Accordingly, the value to generate the management events at a proper frequency is empirically used as the value of the constant h .

[0061]

The value acquired as a result of the process in the step S7 is called as a "long term index" and the long term index corresponding to $(R(n), L(n))$ are called as a "long term index(n)". A series of the long term indices (n) having the long term index (n) as the last one, namely, ... a long term index (n-2), a long term index (n-1), and a long term index (n) are generated by the process of the step S7. The DSP 63 stores these long term indices in the RAM 64 (step S8).

[0062]

The DSP 63 reads out the middle term index (n) and the long term index (n) from the RAM 64 and compares to judge whether the middle term index (n) is equal to or larger than the long term index (n) or not (step S9). The middle term index and the long term index which are read out by the DSP 63 in the step S9 are a middle term index (44099) and a long term index (44099). This comparison process represents that the audio waveform represented by the raw audio data varies with a large amplitude in the middle term at a timing corresponding to the sampling value $(R(n), L(n))$. In other words, when the volume of the sound included within a frequency band of 1 Hz to 100 Hz in the sound waveform of the musical tune increases rapidly, the value of the middle term index exceeds the value of the long term index so that the positive result (hereinafter referred to

as "Yes") is acquired in the comparison process in the step S9.

[0063]

If the positive result Yes is acquired in the comparison process in the step S9, the DSP 63 stores the time at that time in the RAM 64. At the same time, the DSP 63 reads out the time records when Yes was required in the comparison process in the step S9 in the past and judges whether or not there is a record that Yes was acquired in a time period τ in the past (step S10). When the shorter time intervals cause the result of the comparing process in the step S9 to be Yes, the judgment process in this step avoids generation of management events at shorter time intervals in a next step S11 as similarly. If the management events are generated at shorter time intervals, it is difficult to correctly correlate the recorded management events and management events generated by newly acquired audio data in a timing adjusting process mentioned later. The generation of the management events is avoided at time intervals equal to or shorter than the time period τ by the process in the step S10. The value of τ is determined in order to set the proper time intervals of generated management events. Further, the judgment result in the step S10 at an initial judgment becomes No because there is no preceding step S9.

[0064]

When the negative result (hereinafter referred to as "No") is acquired in the judgment process in the step S10, the DSP 63 transmits a management event, which represents that the audio waveform indicating the raw audio data suffices a predetermined condition at a timing corresponding to (R(n), L(n)) after the above described series of processes, to the CPU 62 (step S11).

[0065]

If the comparison result in the step S9 becomes No; the judgment result in the step

S10 becomes Yes; and the process in the step S11 is finished, the DSP 63 stands by until the CPU 62 receives new sample values, namely, $(R(n+1), L(n+1))$, from the music CD drive 1 and stores the sample values in the RAM 64. When the new sample values are stored in the RAM 64 (step S12), the DSP 63 returns the process to the step S1 and executes the process starting from the above mentioned step S1 on the series of sample values which the sample values newly stored in the RAM 64 serve as the last one, namely, the raw audio data $(n+1)$.

[0066]

The sequence in the above step S1 to step S12 is continued by incrementing the number of n by one until the user instructs the recording finish of the performance data. The above is the explanation on the management event generating process. Fig. 6 is a view to show the management event generation when the management event generation process is executed on the real audio data. Moreover, it is assumed that a single stage (Infinite Impulse Response) filter is used as the low pass filter in the step S4 in order to create the graph. It is assumed that the constant h in the step S7 is 4, and the time period τ in the step S10 is 0.55 second.

[0067]

Though there are timings B and C which the middle term index exceeds the long term index immediately after a timing A when a first management event is created in Fig. 6, the management event is created at the timing A only. This is because the timings B and C do not lapse a predetermined time period, namely, 0.55 second after the timing A and the judgment result in step S10 becomes Yes so that the process in the step S11 is not initiated.

[0068]

[1.2.1.4] Generation of MIDI event

While the management event generation processes is executed by the DSP 63, the user starts the performance on the piano 31. In other words, the user listens to a musical tune of the music CD-A which is output from the tone generating portion 4 and depresses keys and manipulates pedals to accompany the musical tune.

[0069]

The performance information on the piano 31 by the user are detected as motions of the keys and pedals by the key sensors 32 and the pedal sensors 33 and is converted into MIDI events by the MIDI event control circuit 34 to be transmitted to the CPU 62 of the controller 6.

[0070]

[1.2.1.5] Recording event in SMF

As mentioned the above, the CPU 62 receives the management events from the DSP 63 during the playback of the music CD-A and the MIDI events from the MIDI event control circuit 34 of the automatic player piano 3. Fig. 7 is an illustrative view showing the relationships between the generated management events and the generated MIDI events with respect to time. The CPU 62 receives the management events at timings which lapse 0.13 second, 0.81 second, 1.45 seconds, ..., respectively, after time measurement starts, namely, from when a first sample value is received from the music CD drive 1. And the CPU 62 receives the MIDI events at timings which lapse 0.49 second, 1.23 seconds, 2.18 seconds, ..., respectively, from when the time measurement starts.

[0071]

The CPU 62 receives the management event, generates a system exclusive event representing the management event, and stores the generated system exclusive event in the RAM 64 after attaching a delta time representing the lapse of time at the receiving timing

of the management event. As similarly, the CPU 62 receives the MIDI event and stores the received MIDI events in the RAM 64 after attaching a delta time representing the lapse of time at the receiving timing of the MIDI event.

[0072]

After finishing the playback of the musical tune of the music CD-A and the user stops the performance on the piano 31, the user depresses a key pad of the manipulation display 5 corresponding to the recording finish of the performance data. The manipulation display 5 transmits a signal corresponding to the depressed key pad to the controller 6. The CPU 62 receives the signal representing the recording finish of the performance data from the manipulation display 5 and transmits the playing stop instruction of the music CD to the music CD drive 1. In response to the playing stop instruction, the music CD drive 1 stops playing back the music CD-A.

[0073]

Subsequently, the CPU 62 reads out the system exclusive event representing the management event and the MIDI events stored in the RAM 64 together with the corresponding delta time, and combines those sets of data in order to create the track chunk of the SMF. Moreover, the CPU 62 attaches a header chunk to the created track chunk in order to create the SMF. Fig. 8 is a view to show the overview of the SMF created by the CPU 62. The CPU 62 finishes creating the SMF and transmits the created SMF to the FD drive 2 together with a writing instruction. The FD drive 2 receives the write instruction and the SMF from the CPU 62 and writes the SMF in the loaded FD.

[0074]

[1.2.2] Playback operation

Subsequently, the operations to play back the SMF recorded by the above

mentioned method and to synchronize the audio data of the music CD with the MIDI data of the SMF will be explained. The music CD used during the playback operation below includes the musical tune same as that of the music CD-A used in the above mentioned recording operation, however, version is different and the performance speeds of the musical tune included in the music CDs is different a little bit. Since audio effects on the master data of the audio data of the music CD are edited, the contents are slightly different from the same musical tune data in the music CD-A and the level of the audio waveform represented by the audio data are different. Accordingly, the music CD used in the playback operation, which will be explained hereunder, is called as a music CD-B in order to discriminate it from the music CD-A.

[0075]

[1.2.2.1] Playback start manipulation

The user loads a music CD-B on the music CD drive 1 and an FD, on which the SMF is recorded, on the FD drive 2. Subsequently, the user depresses the key pad of the manipulation display 5 corresponding to the playback start of the performance data. The manipulation display 5 outputs a signal corresponding to the depressed key pad to the controller 6.

[0076]

The CPU 62 receives a signal instructing the playback start of the performance data from the manipulation display 5 and transmits a transmission instruction of the SMF to the FD drive 2. The FD drive 2 reads out the SMF from the FD in response to the transmission instruction of the SMF and transmits the readout SMF to the controller 6. The CPU 62 receives the SMF from the FD drive 2 and stores the received SMF in the RAM 64.

[0077]

Subsequently, the CPU 62 transmits a playback instruction of the music CD to the music CD drive 1. The music CD drive 1 sequentially transmits the audio data stored in the music CD-B to the controller 6 in response to the playback instruction. The controller 6 receives a pair of data in the left and right channels from the music CD drive 1 for every $1/44100$ second. Herein, the data values received from the music CD drive 1 by the CPU 62 are represented by $(r(n), l(n))$. The ranges of the values $r(n)$ and $l(n)$ and the definitions of n and "sample values" used hereunder are similar to those of $R(n)$ and $L(n)$.

[0078]

[1.2.2.2] Transmission of audio data to tone generator

The CPU 62 receives the sample values, namely, $(r(0), l(0))$, $(r(1), l(1))$, $(r(2), l(2))$, ... from the music CD drive 1 and transmits the received sample values to the tone generating portion 4. The tone generating portion 4 receives the sample values from the controller 6 and converts it to sounds to be output. As a result, the user can listen to a musical tune recorded on the music CD-B.

[0079]

[1.2.2.3] Generation of management event

The CPU 62 transmits the received sample values to the tone generating portion 4 and sequentially stores the received sample values in the RAM 64. The CPU 62 stores a predetermined number of sample values in the RAM 64 and transmits an execution instruction of the management event generation process. The DSP 63 receives the execution instruction and executes the management event generation process, which was explained with reference to Fig. 4, on a series of sample values of the music CD-B sequentially stored in the RAM 64. As a result, the DSP 63 sequentially transmits the

management event to the CPU 62 at a timing when the judgment result in the step S10 in Fig. 4.

[0080]

[1.2.2.4] Playback of MIDI event

On the other hand, the CPU 62 receives first sample values, namely, $(r(0), l(0))$ from the music CD drive 1 and starts time measurement by setting that timing as 0 second. The lapse of time by the time measurement is called as "time T". At the same time, the CPU 62 reads out the SMF from the RAM 64 and sequentially compares the time T at that time with the delta time included in the SMF. When the time T coincides with the delta time and the event corresponding to the delta time is an MIDI event, the CPU 62 transmits the MIDI event to the automatic player piano 3.

[0081]

In the automatic player piano 3, the MIDI event control circuit 34 receives the MIDI events from the CPU 62 and transmits the received MIDI events to the tone generator 35 or the driving part 36. When the MIDI events are transmitted to the tone generator 35, the tone generator 35 sequentially transmits audio data indicative of tones of a musical instrument based on the received MIDI events to the tone generating portion 4. The tone generating portion 4 outputs the sounds of the musical tune in the music CD-B which is played back already and the performance by the musical tone received from the tone generator 35 from the speaker 44. On the other hand, when the MIDI events are transmitted to the driving portion 36, the driving portion 36 drives the keys and pedals of the piano 31 based on the received MIDI events. In either case, the user simultaneously listens to the musical tune recorded on the music CD-B and the performance with the musical tone by the performance information recorded in the SMF.

[0082]

However, since the musical tune recorded in the music CD-B was recorded at a slightly different speed of the musical tune recorded in the music CD-A as mentioned already, the musical tune is offset from the performance by the MIDI events. Fig. 9 is a view to show relationship between the MIDI events and management events stored in the SMF and the management events generated upon playing back the music CD-B and the MIDI events after the timing adjustment process with respect to time. Since the clock frequency used for storing the audio data in the music CD-B is a relatively higher than the clock frequency used for storing the audio data in the music CD-A in the example in the drawing, the musical tune stored in the music CD-B is played back faster than the musical tune stored in the music CD-A upon playing back by the same music CD drive 1. Accordingly, when the MIDI events are transmitted to the automatic player piano 3 based on the delta time stored in the SMF, the automatic performance by the automatic player piano 3 is delayed from the musical tune in the music CD-B. The CPU 62 executes the timing adjustment process explained below on the MIDI events stored in the SMF in order to adjust the time shift between the performance by the MIDI events and the playback of the music CD.

[0083]

The timing adjusting process is a process which adjusts the delta time of the MIDI event based on the generation timing of the management event generated based on the audio data of the music CD-B and the delta time of the management event stored in the SMF. Hereunder, the management event stored in the SMF is called as a "management event A" and the management event of generated based on the audio data of the music CD-B is called as a "management event B".

[0084]

The CPU 62 receives the management event B from the DSP 63 and stores the received timing in the RAM 64. On the other hand, when the time period T and the delta time coincides each other and the event corresponding to the delta time is a management event, the CPU 62 monitors whether the management event B is received during a certain period of time before and after the timing represented by the delta time or not. In other words, the CPU 62 confirms whether there is a record of receiving the management event B during 0.2 second before the timing represented by the delta time of the management event A or not. Subsequently, the CPU 62 monitors whether the management event B is received before lapsing 0.2 second after the timing represented by the delta time of the management event A or not. When the management event B is received around the timing represented by the delta time of the management event A, the CPU judges that the management event A and the management event B are management events generated from corresponding portions of the audio data of the music CD-A and the music CD-B. Then, the CPU 62 multiplies (received timing of the management event B / delta time of the management event A) to a set of delta time of the unexecuted MIDI event and the management event. This is a process which adjusts the delta time in the SMF based on the receiving timing of the management event B. The CPU 62 repeats the adjusting process of the delta time by the end of the musical tune.

[0085]

Fig. 10 is an example of data showing the status of the timing adjusting process. According to the data example, the delta time of the management event A coincides with the time T at 0.13 second. Accordingly, the CPU 62 confirms whether the management event B is received during a period of 0.2 second before that timing or not. Since the first

management event B is received at 0.11 second in this case, the CPU 62 judges that these events correspond each other.

[0086]

Subsequently, the CPU 62 multiplies $(0.11 / 0.13)$ to a set of the delta time of the unprocessed MIDI event and the management event A by using 0.13 second of the delta time of the management event A and the 0.11 second of the receiving timing of the management event B. As a result, the delta time after the first adjustment are as follows: a first MIDI event: 0.41 second, a second management event: 0.69 second, a second MIDI event: 1.04 seconds...

Thereafter, the delta time of the first MIDI event coincides with the time T at 0.41 second and the CPU 62 transmits the first MIDI event to the automatic player piano 3.

[0087]

Since the delta time of the second management event A coincides with the time T at 0.69 second thereafter, the CPU 62 confirms whether the management event B is received during 0.2 second period before such timing or not. In this case, as the second management event B is received at 0.75 second, the CPU 62 judges that these management events correspond each other. As a result, the CPU 62 multiplies $(0.75 / 0.69)$ to the sets of delta time of the unprocessed MIDI event and the management event A as similar to the first management event A. As a result, the delta time after the second adjustment are as follows: a second MIDI event: 1.14 second, a third management event: 1.34 seconds, a third MIDI event: 2.02 seconds...

Since the delta time of the second MIDI event coincides with the time T at 1.14 seconds after that, the CPU 62 transmits the second MIDI event to the automatic player piano 3.

[0088]

Hereunder, the similar processes are repeated until the end of the musical tune, a fourth management event A is ignored in the data example in Fig. 10 because there is not any management event B in time periods of 0.2 second before and 0.2 second after the timing represented by the delta time. As similarly, a eighth management event B is ignored because there is not any management event A in time periods of 0.2 second before and 0.2 after the generation timing.

[0089]

As described in the above, the MIDI event is transmitted to the automatic player piano 3 based on the delta time which the timing adjusting process is underwent, and as a result, the MIDI events are played back at approximately correct timings with respect to the playback of the music CD-B as shown in a lower row in Fig. 9.

[0090]

In contrast to the above mentioned example, when the music tune stored in the music CD-B is played later than the music tune stored in the music CD-A, the playback timings of the MIDI events are adjusted by the similar process. Accordingly, the explanation will be omitted.

[0091]

[2] Second embodiment

In a second embodiment of the present invention, time codes stored in the music CD is used for adjusting the audio data stored in the music CD and the MIDI event stored in the SMF for synchronized playback. Upon the timing adjusting process, the timing adjustment process is executed with a calculated value by using a regression analysis after finishing the management event generation process of the audio data of the music CD

toward the end thereof.

[0092]

[2.1] Music CD drive

Since the whole configuration, the functions of respective elements and the data format of the MIDI data of the second embodiment are similar to those in the first embodiment except a function of the music CD drive 1, the function of the music CD drive 1 is explained only and other explanation will be omitted.

In the second embodiment, the music CD drive 1 transmits the time codes to the controller 6 together with the audio data recorded in the music CD. Other features are the same as those of the music CD drive 1 in the first embodiment.

[0093]

[2.2] Operation

The operation of the synchronized recorder and player SS in the second embodiment differs from the first embodiment in following three points.

(1) In the recording operation of the performance data, the time codes corresponding to the receiving timing of the events are stored as the set of delta time of the management event and the MIDI event stored in the SMF.

(2) First, the audio data of the music CD is played back to the end during the playback of the performance data and the management event generation process is executed on the audio data. A regression line is calculated for the management event as a result of this and the time information stored in the SMF; the delta time corresponding to the delta time is adjusted based on the regression line. After finishing the timing adjusting process, the music CD is played back and the MIDI events are synchronously played back for the playback thereof.

(3) The MIDI events are transmitted to the automatic player piano 3 based on the time clock transmitted from the music CD drive 1 during the playback of the performance data.

[0094]

Other operations in the second embodiment are similar to those of the first embodiment and the detailed explanation will be omitted. It is assumed that the music CD-A and the music CD-B are used for a recording operation and a playback operation, respectively, as similar to the first embodiment in the following explanation. The format of the time code is represented by hour, minute, second and frame and the time information represented by the time code is represented in second as similar to the delta time recorded in the SMF in the following explanation for the sake of the simplicity.

[0095]

[2.2.1] Recording operation

In the synchronized recorder and player SS in the second embodiment, when the user instructs the recording start of the performance data through the manipulation display 5, the audio data in the music CD-A is sequentially transmitted to the controller 6 from the music CD drive 1 together with the time codes.

[0096]

In the controller 6, the CPU 62 sequentially transmits the received audio data to the tone generating portion 4 and the musical tune of the music CD-A is output as sounds from the tone generating portion 4. On the other hand, the CPU 62 sequentially stores the received sample values in the RAM 64 together with the time codes.

[0097]

The CPU 62 stores the predetermined number of sample values in the RAM 64 and transmits an execution instruction of the management event generation process to the

DSP 63. The DSP 63 receives the execution instruction and executes the management event generation process on a series of sample values of the music CD-A which are sequentially stored in the RAM 64. The management event generation process in the second embodiment is the same as the management event generation process in the first embodiment explained with reference to Fig. 4. As a result, the DSP 63 sequentially transmits the management event to the CPU 62 at a timing when the judgment result in the step S10 in Fig. 4 becomes No. The CPU 62 receives the management event and generates the system exclusive event representing the management event. Subsequently, the CPU 62 converts the time represented by the time code received from the music CD drive 1 in the format of the delta time immediately before receiving the management event and after that, correlates the delta time to the system exclusive event represented by the management event to be stored in the RAM 64.

[0098]

On the other hand, the user listens to the musical tune of the music CD-A output as sounds from the tone generating portion 4 and plays on the piano 31. The information by the user performance is transmitted to the CPU 62 through the MIDI event control circuit 34 as the MIDI events. The CPU 62 receives the MIDI events from the MIDI event control circuit 34, converts the time represented by the time code received from the music CD drive 1 immediately before, and correlates the delta time to the MIDI event to be stored in the RAM 64.

[0099]

Thereafter, when the user instructs the recording end of the performance data, the music CD drive 1 stops playing the music CD-A. The CPU 62 reads out the system exclusive event representing the management event stored in the RAM 64 and the MIDI

event together with the corresponding to the delta time and combines the data in order to generate the SMF similar to those shown in Fig. 9. The delta time of the SMF in the second embodiment is based on the time code of the music CD-A and is not based on the measured time of the CPU 62. The SMF generated in such a way is transmitted to the FD drive 2 and is written in the FD loaded in the FD drive 2.

[0100]

[2.2.2] Playback operation

Subsequently, operations for playing back the SMF, which is recorded by the above mentioned method, and for synchronizing the audio data of the music CD-B and the MIDI data of the SMF will be explained.

The user instructs the playback start of the performance data by using the manipulation display 5; the SMF recorded in the FD is transmitted from the FD drive 2 to the CPU 62 and the CPU 62 stores the received SMF in the RAM 64. Subsequently, the music CD drive 1 starts playback of the music CD-B and the audio data and the time code recorded in the music CD-B are sequentially transmitted to the controller 6. The CPU 62 stores the audio data in the RAM 64 together with the time code. However, the CPU 62 does not transmit the received audio data to the tone generating portion 4 and, accordingly, the user does not hear the musical tune of the music CD-B.

[0101]

The CPU 62 stores the predetermined number of sample values in the RAM 64 and transmits an execution instruction of the management event generating process to the DSP 63. The DSP 63 receives the execution instruction and executes the management event generation process on the series of sample values of the music CD-B which are sequentially stored in the RAM 64. As a result, the DSP 63 sequentially transmits the

management event to the CPU 62 at a timing when the judgment result in the step S10 in Fig. 4 becomes No. The CPU 62 receives the management event, converts the time represented by the time code received from the music CD drive 1 immediately before in the format of the delta time and after that, and stores the delta time in the RAM 64.

Hereunder, the management event stored in the SMF is called as a “management event A”; the delta time stored in the SMF is called as a “delta time A”; the management event generated with the audio data of the music CD-B is called as a “management event B”; and the delta time stored upon receiving the management event is called as a “delta time B”.

[0102]

When the playback of the music CD-B comes to an end, the music CD drive 1 finishes the playback of the music CD-B. Subsequently, the CPU 62 reads out the delta time A and the delta time B from the RAM 64 and executes the adjusting process of the delta time as similar to the timing adjusting process in the first embodiment. Fig. 11 shows data examples of the delta time adjustment in the second embodiment. In Fig. 11, the receiving timings of the delta time and the management event B are based on the time codes of the music CD-B and it is different from those in the first embodiment. The adjustment of the delta time is not executed on the MIDI events. Other points are similar to the those in the timing adjustment process in the first embodiment and the explanation will be omitted. The delta time A and the delta time B are correlated each other by the adjustment process of the delta time. A value of the delta time A and a value of the delta time B in a nth pair are represented as $A(n)$ and $B(n)$, respectively. The pair is represented as $(A(n), B(n))$. Accordingly, these are represented as $(A(1), B(1)) = (0.13, 0.11)$, $(A(2), B(2)) = (0.81, 0.75)$, $(A(3), B(3)) = (1.45, 1.36)$, ...

[0103]

Subsequently, the CPU 62 calculates a regression line for the $(A(n), B(n))$ by the least-square method. A regression curve and other approximated curves may be calculated instead of the regression line. Actually, the regression line is calculated for $(A(n), B(n))$ acquired for the audio data of the whole musical tune and it is assumed that nine pairs of data acquired from Fig. 11 are used in order to calculate the regression line.

[0104]

Fig. 12 is a graph showing nine pairs of $(A(n), B(n))$ and a regression line therefor. A formula representing the regression line is $B = 0.9414A - 0.006$. This formula indicates that the starting timing of the performance data of the SMF is delayed from the starting timing of the audio data of the music CD-B with 0.006 second and the performance speed is slower than that with 5.86 % after setting the time code of the music CD-B as a base. Accordingly, the CPU 62 adjusts the timing with respect to the delta time by substituting the value of the delta time of the MIDI event recorded in the SMF for A in the formula of the calculated regression line. The delta time before the timing adjustment and the delta time after the adjustment are shown in Fig. 13. The timing adjustment by the CPU 62 decreases the delta time of each event with 5.86 % and moves them forward with 0.006 second. The CPU 62 renews the delta time of the MIDI events of the SMF with the delta time after finishing the timing adjustment.

[0105]

The CPU 62 finishes the timing adjustment process and transmits a playback instruction of the music CD-B to the music CD drive 1 again. The CD drive 1 starts playback of the music CD-B in response to the playback instruction and the audio data and the time code stored in the music CD-B are sequentially transmitted to the controller 6.

The CPU 62 sequentially transmits the received audio data to the tone generating portion 4 and the tone generating portion 4 outputs the musical tune of the music CD-B as sounds.

[0106]

The CPU 62 sequentially transmits the received audio data to the tone generating portion 4 and at the same time, compares the time information represented by the delta time of the MIDI events with the time information represented by the time code of the music CD-B transmitted from the music CD drive 1, and when they are matched, transmits the MIDI event corresponding to the matched delta time to the automatic player piano 3. The automatic player piano 3 receives the MIDI events and executes the automatic performance associated with the MIDI events by transmitting the audio data of electronically synthesized musical tones from the tone generator 35 to the tone generating portion 4 or by driving the keys and pedals of the piano 31 by the driving portion 36. As a result, the user can listen to the musical tune recorded in the music CD-B and the performance by the performance information recorded in the SMF simultaneously.

[0107]

[3] Modifications

The above mentioned first embodiment, second embodiment and third embodiment are mere illustrations of the embodiments of the present invention, and various modifications are available without departing from the feature of the present invention. Modifications will be shown hereunder.

[0108]

[3. 1] First modification

In the first modification, elements of the synchronized recorder and player SS are not located in the same device and are separated into groups to be located.

For example, they are separable into following respective groups:

- (1) music CD drive 1
- (2) FD drive 2
- (3) automatic player piano 3
- (4) mixer 41 and D/A converter 42
- (5) amplifier 43
- (6) speaker 44
- (7) manipulation display 5 and controller 6

Further, the controller 6 may be separated into a device for recording operations only and a device for playback operations only.

[0109]

The element groups are connected with audio cables, MIDI cables, optical audio cables, USB (Universal Serial Bus) cables and dedicated control cables. The FD drive 2, the amplifier 43 and speakers 44 may be commercially available ones.

According to the first embodiment, the location flexibility of the synchronized recorder and player SS is enhanced and the user does not need to prepare the whole new components of the synchronized recorder and player SS to reduce the cost by preparing the necessary components only.

[0110]

[3.2] Second modification

In a second modification, the synchronized recorder and player SS does not include the music CD drive 1 and the FD drive 2. On the other hand, a communication interface has a function connectable to the LAN (Local Area Network) and is connected to external communication devices through the LAN and WAN. The controller 6 has an HD

(Hard Disk).

[0111]

The controller 6 receives the digital audio data including the audio data and the time codes from other communication devices through the LAN and records the received audio data in the HD. As similarly, the controller 6 receives the SMF created in association with the audio data from other communication devices through the LAN and records the received SMF in the HD.

[0112]

The controller 6 reads out the digital audio data from the HD instead of receiving the audio data and the time codes of the music CD from the music CD drive 1. The controller 6 executes the similar operations on the HD instead of writing and reading out the SMF into or from the FD drive 2.

According to the second modification, the user is capable of transmitting and receiving the digital audio data and the SMF through the LAN to the communication device which is geographically remote therefrom. The LAN may be connected to the wide area communication network such as the Internet.

[0113]

[EFFECTS OF THE INVENTION]

As explained in the above, according to the present invention, the synchronized play back of the performance data is allowed at a correct timing for the audio data of difference versions in which the audio data having different starting points of the same musical tune. Accordingly, a different set of performance data is not necessary for a different version of the same musical tune and the data generation and data management are simplified.

[0114]

There may be a case that recording levels are different in the different versions of the same musical tune, the management event used for adjusting the playback timing of the performance data in the present invention is generated at the same timing irrelevant to the recording level of the musical tune. This is because the two indices used for generating the management event vary in proportion to the recording levels so that the relation with respect to the magnification is unchanged. Accordingly, the audio data of the version having different recording level is synchronously played back with the performance data at correct timings.

[DOCUMENT NAME] ABSTRACT DOCUMENT

[ABSTRACT]

[PROBLEM] To provide a recorder, a player, a recording method, a playback method and program which permit synchronized playback of the performance data at correct timings for plural sets of audio data of the same musical tune having different speeds.

[SOLVING MEANS] A controller 6 records MIDI data of performance through a piano 31, which is played with the playback of a music CD, in an SMF. At this time the controller 6 compares values represented by components equal to or lower than 100 Hz with those equal to or lower than 1 Hz of the audio data of the music CD and stores management events generated as a consequence in the SMF. Subsequently, the controller 6 plays back the MIDI data stored in the SMF together with the playback of the music CD. At this time, the controller 6 generates a management event from the audio data of the music CD, and compares the timings of the management events stored in the SMF and the timings of the generated management events in order to adjust the playback timings of the MIDI data.
